FAQ: Molecular Genetics

Q1: What is the central dogma of molecular biology?

A1: The central dogma describes the flow of genetic information: DNA is transcribed into RNA, which is then translated into protein. While there are exceptions (e.g., reverse transcription in retroviruses), this framework provides a foundational understanding of gene expression.

Q2: What are the different types of RNA?

A2: Several types of RNA play vital roles in gene expression. mRNA carries the genetic code from DNA to the ribosome. tRNA carries amino acids to the ribosome for protein synthesis. rRNA is a structural component of the ribosome. Other non-coding RNAs (ncRNAs) have diverse regulatory functions.

Q3: How do mutations affect gene function?

A3: Mutations can alter the DNA sequence, leading to changes in the mRNA and ultimately the protein's amino acid sequence. This can result in a non-functional protein, a protein with altered function, or no change at all (silent mutation). The severity of the effect depends on the type and location of the mutation.

Q4: What is PCR (Polymerase Chain Reaction)?

A4: PCR is a laboratory technique used to amplify a specific DNA sequence. It involves repeated cycles of heating and cooling, allowing DNA polymerase to replicate the target sequence exponentially. PCR is widely used in molecular biology research, diagnostics, and forensics.

Q5: What are genetically modified organisms (GMOs)?

A5: GMOs are organisms whose genetic material has been altered using genetic engineering techniques. This allows for the introduction of desirable traits, such as pest resistance or enhanced nutritional value. The use of GMOs is a subject of ongoing debate.
